TITLE: The Absorption of Gamma Rays by Sedimentary Rocks
(O pogloshchenii gamma-luchey osadochnymi porodami)

PERIODICAL: Prikl. geofizika, 1956, Nr 15, pp 135-139

ABSTRACT: The relationship of the absorption coefficient of gamma rays with the energy of 1.25 Mev (isotope Co⁶⁰) to rock density was proved experimentally. A source of gamma rays consisting of rock with a thickness $x \geq 3$ cm and an AMM-12 counter were placed in a lead chamber with walls 5 cm thick. The distance from the source to the sample was sufficiently great, in comparison to the dimension of the latter, to allow us to consider the gamma rays passing through the sample to be parallel. The counter rested against the sample on the side opposite the source, and was fully covered by the sample from direct radiation. The impulse count was obtained with the help

Card 1/2

15-57-10-14620

The Absorption of Gamma Rays (Cont.)

of apparatus of type "B." The absorption coefficient for the gamma rays was computed from the formula: $\mu = x^{-1} \ln I_0 I^{-1}$, where I and I_0 are the rates of count with the sample present and absent respectively. From the data obtained in measuring samples of clay, sandstone, anhydrite, limestone, and dolomite, it was determined that $\mu \approx 0.5 \rho$, where ρ is rock density. This enabled the author to conclude that gamma-ray absorption for mean energy ($0.5 \div 2$ Mev) for the sedimentary rocks depends on the Compton effect, while the influence of the photoelectric effect and the formation of electron-positron intervals are negligible. The fact that μ changes only with ρ , and also the lack of influence exercised by the mineral composition of rocks, make it possible to carry gamma-gamma logging. In interpreting gamma-log curves, it should be taken into consideration that the change in the intensity of gamma radiation should be more abrupt at the contact of the radioactive stratum with a zone of large density, while the change should be more gradual at the contact with a stratum of a lesser density. For this reason, the anomalies shown by gamma-log curves may exhibit asymmetric shapes.

TITLE: Deformation of Aluminum - Bath Cathode Blocks in the
Electrolysis Process. (Deformatsiya katodnykh blokov
alyuminiyevykh vann v protsesse elektroliza)

PERIODICAL: Tsvetnye Metally, 1957, no.2, pp. 44 - 51 (USSR)

ABSTRACT: As aluminum baths continue to increase in size the accurate determination of the deformation of carbonaceous materials under realistic conditions has become more urgent. Details are given of apparatus developed for this by the authors and experimental results obtained with it are presented. The method enables deformation of cathode blocks to be measured directly during electrolysis of cryolite - alumina melts and the authors suggest that such measurements can be used to evaluate the stability of carbon cathode blocks. The effects studied include impregnation with electrolyte, composition of block, the molar na F/AI₂ ratio in the electrolyte, additions to the electrolyte of CaF₂, temperature, current density, carbide formation and applied mechanical load. From the results obtained a more thorough appreciation of the interaction between cathode blocks and various components of the bath is reached. Besides tabulations the results are shown graphically as relative deformation time for different levels of the factors studied.

TITLE: Influence of the Composition and Properties of Cathode Blocks on the Service Life of Aluminum-cell Floors (Vliyanie sostava i svoystv katodnykh blokov na srok sluzhby podiny aluminievogo elektrolizera)

PERIODICAL: Byul. tsvetn. metallurgii, 1957, Nr 8, pp 76-80

ABSTRACT: Various methods are used to show that Na precipitated in the cathode region reacts actively with carbon blocks and causes deformation thereof. In the action of Na upon cathode blocks, the degree of destruction depends upon the structural characteristics of the C material of which the cathode blocks are composed. Thus, the coefficient of deformation of petroleum coke in electrolysis is 31.5, that of pitch coke is 25.0, that of foundry coke is 23.7, that of carbonized anthracite coal 6.6, and of graphite 1.25, and disintegration in Na fumes, in terms of petroleum coke taken as 100%, is respectively 80-86, 70-77, 20-31, and 1.5-2.0. This difference among C materials depends upon the degree of molecular ordering of the

Card 1/2

SOV/137-58-8-16636

Influence of the Composition and Properties of Cathode Blocks (cont.)

hexagonal lattices of the graphite which constitute the basis of the structure of the C materials under examination. At one of the aluminum plants the average service life of baths made of blocks in which petroleum coke is used as filler is 27 months, and that of baths using extruded graphite blocks is 44 months. If the C materials be arranged in a series of declining deformability and destructibility during electrolysis - petroleum coke, pitch coke, carbonized anthracite coal and graphite - the sequence referred to above is arrived at. On the basis of industrial-scale experiments conducted in accordance with the results of the investigations described, the addition of 20-25% artificial graphite or 10-12% flake graphite to the mix used for extrusion of cathode blocks is to be deemed optimal.

TITLE: Effect of Thermal Factors on the Life of Aluminum-cell Floors
(Vliyanie termicheskikh faktorov na stoykost' podiny alyuminii-
veykh elektrolizerov)

PERIODICAL: Tr. Vses. alyumin.-magn. in-ta, 1957, Nr 39, pp 337-356

ABSTRACT: The rapid heating and the high value of the thermal gradient in the heating of various types of cathode blocks does not affect their strength. Tests for "thermal shock", performed by immersion of a cold specimen (halfway) into molten CaF_2 at 1500°C , demonstrate the high heat stability of carbon blocks (CB). Preliminary heating to high temperature (1750°C) increases the life of CB. When specimens of various types of cathode blocks and other carbonaceous materials were heated ten times to 1000° and chilled in cold water each time, no destruction resulted. However, the electrical resistivity of the specimens rose 5% after these 10 alternations of thermal condition, and the mechanical strength rose as well. Under the influence of Na, the specimens that had been tested for heat stability

Card 1/2

SOV/137-58-8-16637

Effect of Thermal Factors on the Life of Aluminum-cell Floors

underwent less destruction than those not previously subjected to the effects of heat. Petroleum- and foundry-coke specimens showed maximum firing shrinkage when brought to 700°, shrinkage of industrial cathode blocks being negligible. Heating to 950° does not reduce the mechanical strength of CB, but increases it considerably. In the 20-850° interval, the coefficient of linear expansion of CB that had not yet been used as cathode material was $(2.0-2.6) \cdot 10^{-6}$. The magnitude of the coefficient of expansion of blocks that had already seen use as cathodes was considerably higher. These blocks underwent considerable thermal deformations. The results of the investigations provide definite confirmation of the high heat stability of CB and the erroneousness of ascribing the destructive effect to "thermal shock", temperature gradients within the body of the block, or to "overheating" of carbonaceous materials when fired prior to the starting of the bath. The coefficient of linear expansion of the electrolytes used in industry is $(27-30) \cdot 10^{-6}$ in the 300-800° interval. This value is 12-15 times as high as the coefficient of thermal expansion of CB. The most destructive influence is that of temporary shutting-off ("freezing") of operating baths with carbonaceous bottoms subject to Na effects and impregnated with electrolyte. At one plant, the average service life of baths that had been "frozen" was only 542 days, while those not subjected to "freezing" lasted 1145 days.

TITLE: Employment of Sodium Absorption by Lead to Study Certain Phenomena in the Vicinity of an Aluminum-bath Cathode (Pri-meneniye sposoba pogloshcheniya natriya svintsem dlya izucheniya nekotorykh yavleniy v oblasti katoda alyuminiyevoy vanny)

PERIODICAL: Tr. Vses. alyumin.-magn. in-ta, 1957, Nr 39, pp 357-367

ABSTRACT: Investigations performed in 1951-1952 were the first to determine that metallic Na is the basic destructive agent working upon the carbon cathode blocks of an Al bath. In this connection an experimental study is made of the amount of Na penetrating into carbon blocks in accordance with various cathode-process conditions. It is established in passing that Na penetrating through the carbon cathode reaches the fireclay brick and is absorbed thereby with reduction of the oxides and formation of a dark vitreous mass. Comparison of the properties of the different C materials shows that at 810°C, Pb in a carbonized-anthracite coal vessel contains 2.87% Na, while its Na content

Card 1/2

SOV/137-58-8-16638

Employment of Sodium Absorption by Lead (cont.)

is 1.6% in a foundry-coke vessel, and 3.85% in a pitch-coke vessel when these vessels are held in Na fumes. Upon electrolysis, if the Pb is enclosed in a carbon cathode, the amount of Na in the cathode Pb was 0.025, 0.32, 0.49, and 2.67%, respectively, with electrolyte NaF:AlF₃ ratios of 1.7, 2.5, 3.0, and 5.0. The electrolysis was run with Al₂O₃ and Al in the electrolyte. If the electrolyte does not contain Al₂O₃ but does contain Al, the quantity of Na in the cathodic Pb declines. Industrial practice has established that addition of CaF₂ to the electrolyte has a favorable effect upon the life of a carbon cathode. Experiments in displacing sodium by Al in various electrolytes in the presence of CaF₂ and in its absence show that the amount of Na precipitated declines because of the presence of CaF₂ in the electrolyte, and that favorable conditions for cathode-block service are thereby created.

Orig Pub.	: Kohasz. lapok, 1958, 13, No 7, 322-326	
Abstract	: Effect of sodium vapors on the destruction of carbon cathodes (C) was investigated. These subject to greatest destruction are C derived from petroleum coke; the most stable ones are graphite C. The degree of destruction is inversely proportional to temperature. For the determination of a degree of deformation of C as affected by Na and for the variation of Na quantity penetrating into C, special apparatuses were used.

AUTHOR: Rapoport, M.B.

TITLE: Techniques of Ultrasonic Modelling of Seismic Processes

PERIODICAL: Izvestiya Akademii nauk SSSR, Seriya Geofizicheskaya,
1960, No. 9, pp.1309-1315

TEXT: The author deals with ultrasonic modelling of seismic waves using two identical piezoelectric transducers, one of which serves as a radiator and the other as a receiver. A short electric pulse is applied to the radiator, producing natural vibrations of the piezoelectric crystal. The vibrations are passed along a two-dimensional model to a receiver which is connected to a wide-band amplifier and an oscilloscope. The author discusses formation of wave pulses, directional properties of transducers and suppression of Rayleigh waves. The author used a "seismoscope" Y3C-2 (UZS-2) with an amplifier modified by introduction of one-section II-filters. The desired frequency and pulse form (Fig.1) were obtained by using an appropriate filter. The use of filters for suppression of natural vibrations of piezoelectric transducers avoided the dependence of the pulse form on the degree of damping

Card 1/3

86223

S/049/60/000/009/001/004
E201/E191

Techniques of Ultrasonic Modelling of Seismic Processes

of transducers, on the contact between the transducers and the model, and on other factors. The filters ensured reproducibility of the oscillograms. Suppression of natural piezoelectric vibrations of transducers by means of filters made it possible to use any piezoelectric crystals, including those poorly matched with the model. Using piezoelectric transducers at frequencies much lower than their natural frequencies, it was possible to avoid undesirable directional characteristics (Figs 2, 3) so that the transducers could be regarded as point sources. Surface (Rayleigh) waves could be partly suppressed (Fig. 4) by coating the models with a thin layer of plasticine; further suppression of these waves (Fig. 5) could be obtained by placing of one of the transducers below the surface of the model. The author deals only with two-dimensional models, but filters can be used also in three-dimensional solid and liquid models. There are 5 figures and 3 Soviet references.

TITLE: On the problem of the automatic construction of seismic profiles

SOURCE: Prikladnaya geofizika (sbornik statey), no. 28, 1960, 3-9

TEXT: Automatic construction of seismic profiles is now possible through the use of reproducible optical and magnetic records. Non-Soviet technical publications of recent years have dealt with numerous types of automatic profile construction devices. Although these instruments differ in their data input systems (optical and magnetic records), computation systems (mechanical, electromechanical, and electronic), and in the form in which the results are obtained (on a time or depth scale), all are still based on the same principle. In the alternate reproduction of field records, a kinematic time variable correction for the distance from the shot point, which results in the straightening of the hyperbolic cophasal axes on seismic tapes, is introduced into the time scale. This kinematic correction

TITLE: The relation of the velocity of elastic longitudinal waves to certain physical properties of sedimentary rocks

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 11, 1961, 6,
abstract 11A55 (V sb. Prikl. geofizika, no. 29, M.,
1961, 12 - 19) ✓

TEXT: The results are described for studying the velocities of longitudinal waves in specimens of sedimentary rocks for boreholes on the South Emba uplift and the Mangyshlak peninsula by the ultrasonic impulse method. On the whole the data of the velocity measurements coincided with the results of the recoil coefficient determinations; the presence of the relation of the velocity characteristics to the porosity, density, and electric resistance was confirmed. However, the study of the influence of dampness on the velocity in sandstone specimens led to new conclusions. The complex cha-

TEXT: Ordinary methods of interpreting the reflection seismograms obtained in geophysical prospecting by correlating several traces are based on the assumption of specular reflection at the interfaces. Inter alia, the PHM (RNP) method has revealed the non-specular character of the reflection at many important types of interface. In the article, a relatively simple theory is developed to account for what happens when a plane wave of a single frequency arrives at a "rough" interface, idealized as a sinusoidal ripple parallel to one direction in an infinite plane sheet. Some generalizations on the case of an impulse from a point source arriving at a randomly rough surface are argued on a purely verbal basis. Experiments on a model were carried out and confirmation obtained

On the reflection...

for the predictions of the theory. [Abstracter's note: RNP is described in L. A. Ryabinkin - Rezul'taty i perspektivy primeneniya metoda RNP (Results and Future Uses of the RNP Method) Sb. "Promyslovyye i razvedochnyye geofizicheskiye issledovaniya". Gostoptekhizdat, M., 1960.) and could be translated as "variable directional reception", and is apparently the well-known method of superposing electrically the recorded traces with a variable phase-shift between each, thus generating a signal representing what would have been observed from a line of geophones tilted at an angle to the surface]. The author determines θ_m - the angle between the normal and the direction of the subsidiary reflection of order m - from

$$\sin \theta_m = \sin \theta + m \frac{\lambda}{i}. \quad (1)$$

where θ = angle between the normal to the 'mean' interface and the direction of specular reflection, λ = wavelength.

Card 2/10

22.21

S/049/01/000/002/002/012
D242/D301

On the reflection...

If $\sin \theta_m > 1$, such a mode is rapidly attenuated away from the interface. The use of ray geometry and plane wave theory is justified by appealing to the condition that $h \gg l$ so that only a very small part of each "ripple" of the interface is involved in reflection. The author then establishes an equation for N by arguing that the path difference between the rays from the center to the edge of the reflecting area must not exceed $\lambda/4$. This leads to Eq (2)

$$N = \frac{Vh}{l} + 1. \quad (2)$$

where h = depth from surface to 'mean' interface, taken as parallel to the surface, l = periodical length of the roughness of the interface, N = number of periods of roughness in first half-period zone. If N is sufficiently large for every frequency component in a wavelet, the plane-wave solution can be generalized to apply also to an impulse from a point source. Since the arrangement measures the apparent phase or group velocity in the line of observation, if v is the velocity of compressional waves in the upper medium

Card 3/10

22424
S/049/61/000/002/002/012
D242/D301 X

On the reflection...

Abstracter's note: Shear waves are ignored as being of much smaller amplitude under the particular conditions and v_ϕ is the apparent phase velocity then

$$v_\phi = \frac{c}{\sin \theta_m} \quad (3)$$

For the author's purpose

$$\lambda_\phi = \frac{\lambda}{\sin \theta_m} \quad (5)$$

The geometry leads to

$$\operatorname{tg} \theta + \operatorname{tg} \theta_m = \frac{x}{h} \quad (6)$$

where x = distance along the surface from source to geophone and for small θ , θ_m

$$\sin \theta_m = \frac{xl + m \lambda h}{2hl}$$

Card 4/10

221.2h

S/049/61/000/002/002/012
D242/D501

On the reflection...

and hence

$$v = \frac{2h1v}{x1 + m} - \frac{2h1vf}{x1f + mvh} \quad (6a)$$

$$\frac{dv}{d} = -\frac{vm}{x1}, v_{gr} = \frac{2vh}{x} \quad (7)$$

where v_{gr} is the apparent group velocity. Since usually the arrival time of an impulse is taken to be that of the fastest rising or first wave of the group, the author argues that v_{gr} is that appropriate to f_2 , the upper frequency limit of the spectrum of the impulse. Using the symbol $t_{gr}(x)$ for the arrival time at a geophone placed at x , by integration of Eq. 7 there results

$$t_{gr}(x) = \frac{x^2 + b}{4vh} \quad (8)$$

Card 5/10

22424

S/049/61/000/002/002/012
D242/D301

On the reflection...

The constant b is derived from the condition on t_{gr} at $x = 0$.
 At this point the principal wave and subsidiary wavelets coincide
 so that

$$\sin \theta_m = -\sin \theta = \frac{m\lambda}{2l} = \frac{vm}{2lf} \quad (8a)$$

and

$$\frac{t_{rp}(0)}{t_f} = \frac{2h}{v \cos \theta} = \frac{2h}{v \sqrt{1 - \left(\frac{mv}{2lf}\right)^2}} \approx \frac{2h}{v} \left(1 + \frac{m^2 v^2}{8l^2 f^2}\right). \quad (9)$$

and after straightforward reduction

$$t_{gr}(x) = \frac{x^2}{4vh} + \frac{2h}{v} + \frac{m^2 vh}{4l^2 f^2} = \frac{x^2}{4vh} + \frac{2h}{v} + \Delta t \quad (10)$$

By putting $m = 0$ in (10) the solution for specular reflection is

Card 6/10

S/049/61/000/002/002/012
D242/D301

On the reflection...

obtained as usual, the arrival time being denoted by t_{refl} . By using (6a), the time displacement of the subsidiary wavelets from a base line of length $x - t_m$, may be derived from

$$\frac{\delta t_m}{\delta x} = \frac{1}{r_0(f_0)} = \frac{x}{2ch} + \frac{m}{2f_0 l}. \quad (11)$$

f_0 is the average or apparent frequency of the impulse. By putting $m = 0$ in this the author obtains δt_{refl} which is the time displacement of the specular reflections from a base-line δx and hence

$$\delta t_m - \left(\delta t_{refl} \right) = \frac{m \delta x}{2f_0 l} \quad (12)$$

holds along the whole fixed line of observation. These results describe the appearance of all the geophone traces within the prescribed limitations. Besides the specularly reflected wave there is a whole series of subsidiary wavelets. Each of these is propagated along the line of observation with dispersion,

Card 7/10

S/049/61/000/002/002/012
D242/D301

On the reflection...

which leads to the appearance of short lines of constant phase whose gradient is given by (11), making a constant angle given by (12) with the envelope maximum of the group, which is displaced by Δt from the specular reflection. Experiments were carried out with a laboratory adaptation of RNP using barium titanate transducers on the edge of a plexiglass sheet 1300 x 750 x 5 mm. One edge was sawn appropriately to give a periodic reflecting boundary. The opposite edge carried an 80 cm line of 41 receivers and 5 "explosion" points. The traces showed a characteristic frequency of about 40 kc/s, corresponding to a wave-length of about 5.5 cm. The main features of the apparatus have already been described by M. B. Rapoport (Ref. 11: K metodika seismicheskogo ul'trazvukovogo modelirovaniya. Izv. AN SSSR, ser. geofiz., No. 9, 1960). The features of the above theory were well demonstrated. The only quantitative comparison was in a series of three experiments with $l = 8$ cm and a pattern of semicircular "bites" taken out of the edge of radii 1:1.8 and 2.5 cm. Here Δt (obser.) was $\pm (21-24)$

Card 8/10

S/049/01/000/002/002/012
D242/D301

On the reflection...

μ sec and Δt (calc) was 22 mm μ sec. Hence $m = \pm 1$. It was shown that higher orders would have been expected to be attenuated. AUTHORS: Rapoport, M. B., Kozlov, V. M.

TITLE: Reduction of iron-titanium concentrates in the solid phase without melting (I. Communication)

PERIODICAL: Zhurnal prikladnoy khimii, v. 34, no. 4, 1961, 734 - 743

TEXT: Reduction kinetics of iron oxides and titanium dioxide in iron-titanium concentrates were investigated in the solid phase at 1,000 - 1,300°C, i.e., until slag formation. This study was carried out since in literature there is no uniform idea on reduction kinetics in iron-titanium concentrates. The latter contain usually ilmenite ($FeO \cdot TiO_2$), arizonite ($Fe_2O_3 \cdot 3TiO_2$) and perovskite ($CaO_2 \cdot TiO_2$). The reduction process of ilmenite was studied frequently, but different opinions were expressed. Thus Ye. N. Snopova and N. I. Rotkov (Ref. 1: Sovetskaya metall., 12, 11 - 19, 1936) and E. V. Britske et al. (Ref. 2: DAN SSSR, OTN, 2, 9, 1941) assumed that decomposition to FeO and TiO_2 occurs before iron suboxide reduction. Contrary to this opinion V.K. Antonov (Ref. 3: Khimiya i tekhnologiya redkikh elementov (Chemistry and technology of rare elements) Ural'skiy filial AN SSSR, Sverdlovsk, 81 - 94, 1958), G. I. Chu-

Reduction of iron-titanium concentrates

Farev et al. (Ref. 4: Tr. inst. metall. AN SSSR, Ural'skiy filial, 2, 9 - 40, 1958) and A. S. Tumarev (Ref. 8: Sb. "Problemy metallurgii" ("Metallurgical problems"), Izd. AN SSSR, M., 23 - 28, 1959) estimated that reduction of complex oxides occurs without preceding decomposition. Another problem is the question if reduction of oxides occurs more intensively in liquid or solid state, and if the reduction rate of ferrous oxide is considerably higher in liquid than in solid slag. Therefore in the present work the interaction between solid carbon (anthracite) with iron and titanium oxides was investigated in three iron-titanium ore concentrates from deposits in Kusinsk, Irshinsk and Samotkansk (Tab. 1,2). The latter contains Fe_2O_3 and no FeO , while the other two contain mainly ilmenite. The test sample was prepared, in general, by mixing 100 parts of concentrate with 13 parts of anthracite (or 9.5 parts for the Samotkansk concentrate), using sulfite liquor as binder for the subsequent briquetting. The briquettes were tested in a silite oven at 1,000, 1,100, 1,200, and 1,300°C by heating the latter by means of an PHO-250-10 (RNO-250-10) autotransformer. In the product Fe_{total} , Fe_{metal} , Ti_{total} and lower titanium oxides ($Ti^{2+} + Ti^{3+}$) were determined. The sum of di- and tri-valent titanium was determined by the improved method described by L. I. Veselago (Ref. 9: ZhAKh, 13, 5, 562 - 566, 1958). From the ob-

Card 2/9

S/080/61/034/004/003/012
A057/A129

Reduction of iron-titanium concentrates

tained results the degree of reduction of iron- and titanium oxides was estimated. The highest reduction rate of FeO has the Kusinsk concentrate containing less TiO₂ and more iron oxides and admixtures (CaO, and MgO) than the other concentrates. The lowest reduction rate shows the Irzhinsk concentrate, having bigger grains and less admixtures than the other two. Curves showing the effect of duration of a constant 1,000°C temperature have two segments; until 0.5-0.8 hours the kinetic range of the reduction process and above 0.5-0.8 hours the diffusion range. The change from kinetic to the diffusion process is due to the decrease in contact surface between the ore and anthracite. Tests with bigger charges, using anthracite and petroleum coke were carried out and the advantage of briquetting was demonstrated (Table 3). According to experiments on the effect of exhaust gases on reduction the effect of CO evolved from the briquet should be considered. Thus experiments carried out in the present institute and DMET AN SSSR (Institute of Metallurgy imeni A.A. Baykova) indicated that about 20 % of the total reduction is effected by CO. Considering that reduction occurred in the present experiments in the solid phase to 85 - 90% (10 - 15 % are reduced in liquid phase) and taking into account the results obtained for 1,300°C, the advantage of a reduction in solid phase is evident. Thus statements indicating that the main reduction of iron oxides occurs in the liquid phase are

Card 3/9

26862
8/080/61/034/004/003/012
A057/A129

Reduction of iron-titanium concentrates

erroneous. Results of the experiments on reduction of TiO_2 demonstrate (Figures 5,6,Table 4) that simultaneously with the reduction of iron oxides a considerable reduction of TiO_2 to the oxides Ti_3O_5 and Ti_2O_3 takes place. Contrary to Ref. 3, and 4 the present authors observed that TiO_2 reduction starts already in presence of still considerable amounts of iron oxides. In connection with data given by Zh. L. Vert and M. V. Kamentsev (Ref. 10: ZhWKh, IV, 1, 17, 1959), and V.A. Reznichenko and F. B. Khalimov (Ref. 11: Sb."Titan i yego splavy" (Titanium and alloys), 11 - 15, 1959) the influence of admixtures on the reduction of TiO_2 in artificial mixtures of the type of the investigated concentrates was studied. The results (Table 5) demonstrate that the reduction degree of TiO_2 is lower than in natural iron-titanium concentrates. The present authors assume that in reduction of natural concentrates, by destruction of a complex chemical compound TiO_2 is more active than the free TiO_2 molecule. There are 7 figures, 5 tables and 11 Soviet-bloc references.

ABSTRACT: A practical methodology of seismic exploration for investigating the structure of deposits below salt domes in the central Dnieper-Don basin is described. The first stage of seismic exploration consisted of continuous symmetric profiling with controlled grouping during reception, i.e., first correlated modification of controlled directional reception (RNP) and automatic plotting of records. Subsequent use of the directed plane wave-front method (UPF) made it possible

Card 1/2

ACC NR: AT6028965

to detect reflected waves previously not recorded. Greatest efficiency was achieved by combining UPF and controlled grouping of apparatus for automatic plotting of seismic records. A cross section was constructed from the field data using this method, which shows several boundaries within and below the salt domes. Orig. art. has: 5 figures and 2 formulas.

ABSTRACT: This Author Certificate presents a method for producing seismic controllable guided systems by storage on a photolayer of variable density traces with the reproduction of magnetic seismograms. To separate the useful waves and to suppress the ordinary noise, time shifts compensating the time shifts of the separated waves are introduced into the stored signals. Control by the guided systems is accomplished by the rotation of the recording line by an angle equal to the inclination angle of the co-phase axes of the separated waves.

ABSTRACT: This Author Certificate presents a method for seismic exploration with the use of controlled directional excitation systems (operating along any specified principle) and systems of vibration reception. The method increases the effectiveness of exploration and provides a unique selection of seismic waves from the irradiated objects. The interference systems in the vibration reception are coordinated with interference systems of the vibration excitation. This is accomplished by summing up displacements of any number of recordings based on a previously specified relationship which agrees with the vibration excitation principle.

ABSTRACT: This Author Certificate presents a device for summing seismic signals, containing a magnetic drum with reproducing heads, signal amplifiers, step probes, a summing delay line, a summed signal amplifier, a chart recorder, a chart drum, and a time relay. To speed the processing and analysis of material with production of grouped tapes, the coil of the step probe switching the magnitude of the summation time shift is connected through a pulse frequency divider to the coil of the step probe switching the summation base center (see Fig. 1). To obtain summed tapes with the summation base length increased in time, the extremes of the summed channels are connected to the delay line by relay contacts controlled by the time relay.

ABSTRACT: Author's certificate no. 182901, dated 10 April 1965, has been issued to
L. D. Raykher, M. B. Rapoport, N. V. Cherkasskiy, M. I. Chervonskiy and
Yu. V. Yuzevich of the Ukrainian Scientific Geological Prospecting Institute
for a method described as follows: "A method for constructing temporal
seismic cross sections, using a single-track multichannel magnetic record.
It differs in that for the purpose of increasing the quality of the repro-
duced material and speeding up the processing rate the rotating drum is ex-
posed along its generatrix to seismic signals which are displayed on the
screen of a cathode-ray tube; scanning begins in response to appearance of
the time mark of a shot; transition from trace to trace is accomplished by
rotation of the photo drum." [JPRS: 37,397]

TITLE: A method for adding seismic signals. Class 42, No. 182352

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 11, 1966, 80

TOPIC TAGS: seismology, light modulation, nonelectric signal equipment, signal processing

ABSTRACT: This Author's Certificate introduces a method for adding seismic signals by synchronous storage on a light sensitive layer exposed by a long writing line with successive brightness modulation by signals which are reproduced channel by channel. The procedure is designed for addition of reflected signals with hyperbolic cophase axes. During reproduction of each channel, the writing line is rotated through an angle which is determined by the time of arrival of the waves, their rate of propagation and the distance from the point of the explosion to the point of reception.

TITLE: A device for automatically analyzing seismograms and constructing seismic profiles. Class 42, No. 182349

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 11, 1966, 79

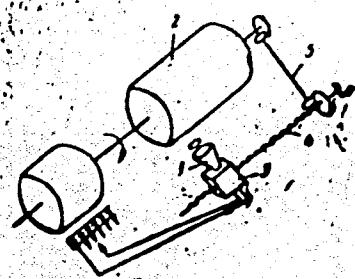

TOPIC TAGS: seismography, cathode ray tube, seismic modeling

ABSTRACT: This Author's Certificate introduces: 1. A device for automatically analyzing seismograms and constructing seismic profiles. The unit is based on Author's Certificate No. 166503. Efficiency of analysis is improved by mounting a cathode ray tube on a carriage which is moved along a photodrum by a worm gear or ratchet turned by the shaft of the photodrum. 2. A modification of this device in which measurement quality is improved by connecting a sawtooth generator through a programmed amplitude regulator to the vertical deflection system of the cathode ray tube.

TOPIC TAGS: seismic modeling, seismic prospecting, seismic wave, acoustic reflection, acoustic refraction

ABSTRACT: A short description is given of seismic modeling experiments and data-processing methods. Most of the research was conducted using two-dimensional models with various differently shaped boundaries (sinosoidal, semicircular, triangular, etc), i.e., with geometrically rough boundaries. Waves analogous to diffraction spectra of the highest order were registered, together with waves reflected from the middle plane of the boundaries (mirror type reflection). The properties of these waves and their usefulness in seismic prospecting are described. Investigations of reflection from physically rough boundaries with periodically variable coefficients of reflection have been initiated. The modeling of waves refracted from rough boundaries of liquid-

TITLE: Role of frequency filtration in seismic modeling

SOURCE: AN SSSR. Institut fiziki Zemli. Geoakustika; ispol'zovaniye zvuka i ul'tra-zvuka v seismologii, seismorazvedke i gornom dele (Geoacoustics; the use of sound and ultrasound in seismology, seismic prospecting, and mining). Moscow, Izd-vo Nauka, 1966, 64-68

TOPIC TAGS: seismic modeling, ~~ultra-sound~~, frequency filtration, seismoscope, piezoelectric crystal, electric filter, high frequency

ABSTRACT: During ultrasonic seismic modeling, the presence in the piezocrystals of several modes of oscillations including parasitic oscillations have been observed to affect the pulse shape. The several methods of forming and damping the natural oscillations of piezocrystals now in use involve the introduction of frequency filters into one or another section of the electroacoustic track of the model. Therefore, they may all be replaced by the action of universal electric filters connected in front of the source or behind the receiver. In this way the similarity between the wave picture in the model and that in nature is preserved. It is recommended that, in modeling with weakly absorbing materials, the use of higher frequencies with sharp frequency cutoff be considered. Universal electric filters, being a simple means of controlling pulse shape, will broaden modeling

No. 189165

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 23, 1966, 77

TOPIC TAGS: seismograph, seismologic instrument

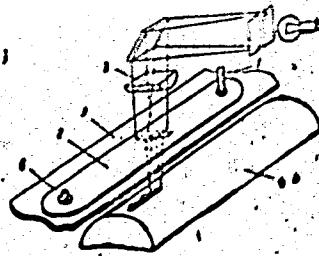

ABSTRACT: This Author Certificate presents a device for converting seismograms into variable height recordings, which contains a pantograph, an illuminator, and a photodrum. To increase the rate of processing seismograms, a drive pin coupled with a movable screen is mounted in the pencil socket of the pantograph (see Fig. 1). The illuminator and a rod which is the axle of rotation of the movable screen are mounted on a plate which can be moved along the generatrix of the photodrum.

AUTHOR: Rapoport, M. B.; Ryabinkin, L. A.

TITLE: A method for making seismograms by controlled directional reception of seismic waves. Class 42, No. 171602

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 11, 1965, 86

TOPIC TAGS: seismography, electronic measurement

ABSTRACT: This Author's Certificate introduces: 1. A method of making seismograms by controlled directional reception of seismic waves. The process is accelerated and the equipment is simplified by feeding the signals of the individual traces of the seismogram which are being reproduced through channels to a number of recorders where these signals are inscribed on a material which can be stored. The inclination of the recorder line to the recording direction varies with the change in the number of the channel being integrated, so that the signals are stored in various locations on the tape with various displacements. 2. A modification of this method

Card 1/2

L 56674-65
ACCESSION NR: AP5017853

in which provision is made for obtaining continuous values of the time shifts between the signals being stored, and for improving the accuracy of the wave shift reading. A recorder is used for projecting a luminous band onto a rotating photo-sensitive drum. The inclination of this band is determined by the number of the channel being integrated, while the brightness of the illumination is modulated by the signals. 3. A modification of this method in which the storage tape is made visible. The storage is done on a phosphor with lagging persistence on the screen of a cathode ray tube. The electron beam forms a narrow luminescent band on the screen of the tube in synchronization with the readout of all the seismogram channels. This band changes its inclination at a high frequency in synchronization with the high frequency switching of the channels being integrated.

Ca

Determination of carbon dioxide in air. M. R. Rapoport. Lab. Pract. (U. S. S. R.) 10, No. 4, 27-4 (1941).—The amt. of CO₂ in various layers of air in the chamber used for the analysis is not identical. This is due not only to the different densities of the air, but also to the difference in the densities of CO₂ and air, to diffusion, convection and other phys. processes taking place in the chamber with air under investigation. For obtaining more accurate results in the determ. of CO₂ it is necessary to analyze all the air of the chamber and to take the mean of these values. If all air of the chamber cannot be analyzed (as is the case in using microapp., dynamic app., or in taking air samples in Douglas bags) it is necessary to make analyses of 3 small samples of air taken from the upper, medium and lower layers of the chamber and use their mean value.

The 25th Anniversary of the Founding of ORGRES (K 25-letiyu so
dnya osnovaniya ORGRES)

PERIODICAL:

Elektrichestvo, 1958, Nr 5, pp. 88-89 (USSR)

ABSTRACT:

In May 1958 it will be 25 years since the State Trust for the organization and rationalization of regional electric power plants and networks (ORGRES) of the Ministry for Electric Power Plants has been founded. The basic task to be performed by ORGRES is to render technical aid to plants in putting into operation and introducing new equipments for power engineering in order to increase the safety and economy of these plants. ORGRES has great experience in this field and worked out numerous schemes and constructions. The measures recommended are published by ORGRES as well as by the Ministry for Electric Power Stations. In the course of 25 years more than 200 electric power stations were able to start operating with the aid of ORGRES. The most important achievement during recent years was starting operation of the Kuybyshev hydraulic power station. ORGRES developed a number of measuring devices, published instructions for electrical equipment, and carried out work in connection

Card 1/2

The 25th Anniversary of the Founding of ORGRES

105-58-5-22/28

with safety measures to be undertaken in connection with the automation of systems. Also a number of recommendations for the reduction of losses in networks, securing the necessary voltage, and for the economical distribution of active- and reactive loads were elaborated by ORGRES. Such problems as the reduction of staffs in substations and changing over to operation without the necessity of a permanent control of the steering panel are solved. On the Khot'kov test stand the staff is trained for building- and assembly work in connection with the 400 kV long-distance lines. The work carried out by ORGRES is coordinated with that performed by the Institutes (VEI, ENIN, NIIPT, VNIIE). ORGRES developed telemeters, for which achievement V.I.Ivankin, V.Ye.Kazanskiy, G.P.Minin and N.P.Lapshov were awarded the Stalin Prize. Among the new telemeters the type T40-53 deserves to be mentioned, which was developed on the basis of T40-3. At present an apparatus for automatic frequency- and power control developed according to the ORGRES method is being tested in the Ural power engineering systems and in the electric power stations of the Belorusenergo.
